Renal tubular acidosis (RTA) type 2, also called proximal renal tubular acidosis, is characterized by hyperchloremic metabolic acidosis due to the impaired reabsorption of bicarbonate (HCO$_3^-$) in proximal tubules. It can be due to an isolated defect or part of a generalized defect (Fanconi syndrome). Rickets/Osteomalacia is more common and treatment is usually difficult. RTA type 3 is designated when the combined features of both type 1 and type 2 RTA are present. In this article, the etiology, pathophysiology, symptoms, diagnosis, differential diagnosis, treatment and prognosis of renal tubular acidosis type 2 are described.

Definition

Renal tubular acidosis is a group of disorders characterized by the failure of kidneys to reabsorb the bicarbonate ion and excretion of hydrogen ion resulting in acidosis and hypokalemia.

Proximal RTA, also called RTA type 2, is characterized by an impaired proximal tubular acidification mechanism in the kidneys, which is due to a reduced reabsorption of HCO$_3^-$ in proximal tubules. Term RTA type 3 is used when features of both type 1 and type 2
RTA are present.

**Epidemiology of Renal Tubular Acidosis Type 2 and 3**

The exact prevalence of RTA type 2 and type 3 are unknown. It may occur as a single entity or a part of a generalized dysfunction (e.g. Fanconi’s syndrome). Isolated primary proximal RTA is rare. Type 3 RTA is extremely rare.

**Etiology of Renal Tubular Acidosis Type 2 and 3**

**Isolated proximal acidification defect**

**Primary causes:**

- Sporadic forms
- Inherited forms:
  - **Autosomal dominant form:** Defect in NHE3, associated with short stature and osteomalacia.
  - **Autosomal recessive form:** Defect in CA-II, associated with cerebral calcification and mental retardation.
  - **Autosomal recessive form:** Defect in NBC1, associated with mental retardation, ocular manifestations (band keratopathy, cataract, and glaucoma), short stature, defective teeth, and basal ganglia calcification.
- Transient phenomenon during infancy.

**Secondary causes (carbonic anhydrase deficiency)**

- **Drugs:** Acetazolamide, sulfanilamide, and mafenide

**Generalized PCT defect (Fanconi syndrome)**

**Primary causes:**

- Inherited renal disease (Idiopathic Fanconi).
- Cystinosis, Wilson disease – the most common causes.
- Tyrosinosis, metachromatic leukodystrophy, glycogen storage disease type 1.
- Hereditary fructose intolerance, galactosemia.
- **Lowe syndrome (oculocerebrorenal syndrome):** X-linked disorder associated with congenital cataract and mental retardation (OCRL gene mutation).
- **Dent disease:** X-linked recessive disorder associated with tubular proteinuria, hypercalciuria, nephrocalcinosis, and nephrolithiasis (chloride channel gene CLCN5 or OCRL gene mutation).
- **Fanconi-Bikel syndrome:** Autosomal recessive disorder associated with impaired utilization of glucose and galactose.

**Secondary causes:**

- **Calcium metabolism disorders:** Vitamin D dependent rickets, vitamin D resistant rickets.
- **Immunoglobulin Disorders:** Amyloidosis, monoclonal gammopathy of
undetermined significance (MGUS), light chain deposition disease (LCDD), multiple myeloma, cryoglobulinemia.

- **Tubulointerstitial diseases:** Medullary cystic disease, Sjogren syndrome, renal transplant rejection, Balkan nephropathy.
- **Drugs and other compounds:** Outdated tetracyclines, gentamicin, valproic acid, ifosfamide, cisplatin, streptozotocin, heavy metals (lead, mercury, cadmium), toluene, tenofovir.
- **Miscellaneous:** Nephrotic syndrome, paroxysmal nocturnal hemoglobinuria, hyperparathyroidism, burns, chronic renal vein thrombosis, hypokalemic nephropathy, kwashiorkor.

Remember, conditions that can cause both proximal RTA and distal RTA include amyloidosis, multiple myeloma, medullary cystic disease, renal transplant rejection, and ifosfamide.

**Type 3 RTA:**

- Autosomal recessive form: In association with osteopetrosis, cerebral calcification, and mental retardation (loss-of-function mutations in the gene encoding carbonic anhydrase II).

**Pathophysiology of Renal Tubular Acidosis Type 2 and 3**

Important renal mechanisms for maintaining acid-base homeostasis include reabsorption of filtered HCO₃⁻ and excretion of nonvolatile acids. Normally, 85—90% of HCO₃⁻ is reabsorbed in proximal tubules and distal segments cause acidification of urine by the reclamation of the remaining HCO₃⁻ and by active secretion of H⁺ in the form of titrable acid, NH₄⁺, and free ions.

In **proximal convoluted tubule (PCT),** luminal Na⁺/H⁺ exchanger (NHE3), Na⁺/K⁺ ATPase, brush border carbonic anhydrase IV (CA-IV), cytoplasmic carbonic anhydrase II (CA-II) and basolateral Na⁺-3HCO₃⁻ cotransporter (NBC1) play an important role in HCO₃⁻ reabsorption. Na⁺/K⁺ ATPase creates negative potential, which favors Na⁺ reabsorption, which is coupled to H⁺ secretion by NHE3. Luminal CA-IV produces CO₂ and H₂O from the secreted H⁺ and luminal HCO₃⁻. CO₂ diffuses into cells of PCT and cytoplasmic CA-II reforms H⁺ and HCO₃⁻. The HCO₃⁻ is reabsorbed into the systemic circulation by basolateral Na⁺-3HCO₃⁻ cotransporter.

Proximal HCO₃⁻ reabsorption is increased by high luminal HCO₃⁻ concentration, high luminal PCO₂, increased NHE3 activity (low extracellular fluid volume, α-adrenergic stimulation, renin-angiotensin-aldosterone axis activation), glucocorticoids, increased luminal electropositivity (high parathormone levels), etc. PCT also synthesizes and secretes NH₄⁺ which is an important buffer.

In **proximal RTA,** there is defective reabsorption of HCO₃⁻ in proximal tubules due to a defect in one of above mechanisms or due to the generalized defect in proximal tubular function (Fanconi syndrome). As a result, threshold serum HCO₃⁻ concentration for reabsorption of HCO₃⁻ from PCT is reduced to less than 15 mEq/L. Ammonia secretion and H⁺ secretion are intact in proximal RTA.

Loss of HCO₃⁻ results in non-anion gap metabolic acidosis (NAGMA). The lost HCO₃⁻ is also accompanied by a cation (K⁺ more than Na⁺). A loss of Na⁺ causes polyuria and
volume depletion, which increases thirst and activates renin-angiotensin-aldosterone (RAA) axis. Aldosterone increases Na⁺ reabsorption, which causes blunting of hypovolemia and increases K⁺ excretion, which aggravates hypokalemia. Increased distal Na⁺ increases distal Ca²⁺ wasting, causing hypercalciuria.

Hypophosphatemia and phosphaturia contribute to rickets. Bone mineralization without rickets may also be seen.

In Fanconi syndrome, due to a generalized PCT defect, there is a urinary loss of bicarbonate, low-molecular-weight protein, uric acid, glucose, phosphate, citrate, calcium, potassium, and amino acids.

Some children with RTA show features of both type 1 and type 2 RTA and hence are diagnosed with type 3 RTA; however, many of them exhibit features of proximal RTA only transiently and evolve into classic distal RTA later. Features of proximal RTA in these children are thought to be due to the immaturity of proximal tubule only; hence, some authorities do not consider type 3 RTA as a distinct entity.

### Symptoms of Renal Tubular Acidosis Type 2 and 3

Children with proximal RTA may be asymptomatic or they may present with symptoms like polyuria and polydipsia. Muscle weakness, fatigue, hypotonia, and constipation may be present due to hypokalemia. Anorexia, vomiting, and dehydration may also be present. Low normal blood pressure is seen due to hypovolemia.

Refractory rickets or osteomalacia is often present, which may be associated with pathological fractures, bone pain, growth retardation, and osteopenia. Growth retardation and a failure to thrive may be seen in children. Unlike distal RTA, nephrolithiasis is absent in proximal RTA.

If associated with the specific syndrome, additional signs and symptoms of the syndrome are present.

### Diagnosis of Renal Tubular Acidosis Type 2 and 3

A hallmark of RTA is non-anion gap metabolic acidosis (NAGMA) or hyperchloremic metabolic acidosis. Important laboratory findings in proximal RTA are low serum HCO₃⁻, hypokalemia (although less severe than that in distal RTA), and variable urinary pH. There may be increased or normal excretion of calcium, citrate, or phosphate in the urine, while there may be decreased or normal excretion of NH₄⁺ in the urine. Serum calcium and serum phosphate are normal. (High-yield information.)

Urine anion gap (UAG) is variable, usually negative in proximal RTA.

Urine pH more than 5.5 suggests a renal acidification defect when the pH is measured in a fresh early morning urine sample.

Urine pH is variable in proximal RTA. Urine is alkaline if serum HCO₃⁻ concentration is more than tubular maximum, while urine pH is less than 5.3 when serum HCO₃⁻ concentration is less than the tubular maximum. Remember that RTA type II and RTA type IV can present with urine pH < 5.5. (High-yield information.)

On performing an ammonium chloride acid loading test, urine pH decreases to less than 5.3 in proximal RTA, which helps to differentiate it from distal RTA.
In proximal RTA, the measurement of urine pH after administration of furosemide also shows a decreased urine pH; however, there are high rates of false-positive and false-negative results in this test.

On performing a sodium bicarbonate loading test, urine PCO₂ is normal (more than 60-70 mm Hg), urine-blood PCO₂ gradient (U-B PCO₂) is more than 20 mm Hg, and fractional excretion of bicarbonate (FEHCO₃) is more than 10-15% in proximal RTA.

In Fanconi syndrome, bicarbonaturia, tubular proteinuria, uricosuria, glycosuria, phosphaturia, citraturia, and aminoaciduria are present.

Differential Diagnoses of Renal Tubular Acidosis
Type 2 and 3
- Other types of RTA
- Other causes of NAGMA
  - Chronic renal failure
  - Extrarenal bicarbonate loss – diarrhea, intestinal fistula, etc
  - Ketoacidosis
  - Lactic acidosis
  - Exogenous administration of Cl⁻-rich solutions
  - Parenteral nutrition
  - Drug toxicity

Therapy of Renal Tubular Acidosis Type 2 and 3
In proximal RTA, the goal of treatment is to increase serum HCO₃⁻ to as close to normal as possible; however, this is usually difficult because of increased bicarbonaturia, polyuria, and hypokalemia associated with bicarbonate administration, due to decreased bicarbonate tubular maximum.

Due to a massive loss of bicarbonate, children with proximal RTA require higher (as high as 10-20 mEq/kg/day) and more frequent doses of oral alkali, in the form of sodium bicarbonate or sodium citrate solution.

Supplementation with potassium and vitamin D is usually required in proximal RTA. As renal activation of vitamin D is defective, calcitriol is the preferred form for vitamin D supplementation. Phosphate replacement may be required in Fanconi syndrome due to phosphate wasting.

Thiazide diuretics are useful in the treatment of proximal RTA as they induce mild volume depletion, enhance proximal reabsorption of sodium, and therefore secondarily enhance the reabsorption of HCO₃⁻.

Children with severe metabolic acidosis (serum bicarbonate less than 12 mEq/L) are given intravenous bicarbonate, after calculation of the required dose of bicarbonate. Half of the required dose is administered over 8 hours and the remaining half dose is administered over the next 24 hours. The required dose is calculated using the following formula:

\[
\text{Required dose} = \text{desired change in serum bicarbonate} \times \text{body weight (kg)} \times 0.6.
\]
Progression and Prognosis of Renal Tubular Acidosis Type 2 and 3

In proximal RTA, although improvement in growth and reduced severity of bone disease are observed with the correction of acidosis, the overall improvement is less impressive in children. Patients with systemic illness experience significant morbidity. **Hyperchloremic acidosis** is considered to be a risk factor for the development of acute kidney injury (AKI) following abdominal surgery.

Complications

Complications may include:

- Rickets
- Osteomalacia
- Failure to thrive
- Kidney stones
- Renal cyst formation

Review Questions

The answers can be found below the references.

1. Which of the following drugs is known to cause both proximal RTA and distal RTA?
   - A. Gentamicin
   - B. Ifosfamide
   - C. Lithium
   - D. Old tetracycline
   - E. Valproic acid

2. Which of the following is a laboratory feature which is seen in proximal RTA, but is not present in distal RTA?
   - A. Hyperchloremic metabolic acidosis
   - B. Hypokalemia
   - C. Negative Urine Anion Gap
   - D. Hypercalciuria

3. Mutations in genes encoding which of the following proteins are associated with autosomal recessive type 3 RTA, osteopetrosis, and mental retardation?
   - A. Luminal Na+/H+ exchanger
   - B. Na+K+ ATPase
   - C. Basolateral Na+/3HCO3- cotransporter
   - D. Brush border carbonic anhydrase
   - E. Cytoplasmic carbonic anhydrase
